TikTok XR Initial Ideation

- **filming tiktok videos**: this would be done when users pick up a photo camera for photos, or a video camera for videos. they can switch to back or front camera mode. they can then wield the camera + take photos / film videos

  ↓ feedback: what if I wanted to set camera up somewhere to record?

  in the environment, have a tripod, which height + position can be adjusted through user physically grabbing tripod neck to extend/ retract tripod height + user physically grabbing tripod to move it around. this allows user to enter a "hands-free mode", as they can place photo/video camera on tripod to take photo/film video.

  ↓ additional considerations: is it redundant to have separate photo + video cameras? the current tiktok photo / video taking interface has 5 modes, "text", "photo", "15 s", "60s", "10 m". but photo + video taking are in the same interface

  have a singular camera, with photo + video capability. the user can use their hands to swipe between modes. there will also be a "reverse" button 🔄 to switch between front camera + back camera

- **scrolling on tiktok**: one of the most popular features of tiktok is the ability to infinitely scroll. in XR, users would be able to do the same thing

  ↓ additional considerations: if they are just scrolling through videos with their hands like on the mobile app, then what is the advantage of XR?

  users are able to infinitely scroll using the controllers. they are able to scroll up + down using the joystick, and pause / play using the button on the main VR controllers. this makes the video watching process less taxing on the hands, and more enjoyable

  ex decided not to go through with this idea, as I think the XR experience I want to develop will use hands as controllers instead of the actual main controllers. this allows users actions to be a lot more intuitive + in line with what they already do in their daily life, allowing less of a learning curve

- **learning tiktok dances**: one common trend on tiktok are dance trends, and there are often new dance trends for new song releases that users can dance along to + film a video. this feature would have the desired video on the left side of the view, and a mirror on the right side showing the users avatar. users would then be able to follow along with the video on the left, + look at their movements on the right to learn the dance

  ↓ user feedback: how can this idea become interactive? the user needs to physically interact with something, for example, a workout game will the user hitting "bubbles" to show the action has been completed

  on the right side with the avatar, there are bubbles / targets for each of the movements, such as where to place their hand + feet. if the user is able to hit the target on time, it means they get the move correct. at the end, they will get a mastery score out of 5 stars, and they are able to keep retrying to get 5/5 stars, in which case they would have "learned" how to dance to the song

- **apply filters/special effects**: something people do when filming videos / taking photos is apply filters on themselves. this can be done in the VR environment by having users interact with a makeup station. when users click on the makeup station, they can apply them by selecting them by swiping through available filters, clicking the selected filter, and applying + repositioning it on their face or on the avatar

  ↓ feedback: if I wanted to change + get rid of it? makeup wipes?

  in the "apply makeup" section, there is a 'go back' arrow < so users can go back to the list of filters, and a 'bin' button 🗑 that users can press to completely remove the filter

  ↓ additional considerations: what about filters that change the environment? for example, those that recolor a photo/video or those that change the background of the avatar

  in addition to filters on the avatar, there will also be filters that can be applied to the spatial VR environment.
